㉖ Safety monitor.

㉗ A monitor system for safety critical situations such as burner control receives at inputs 17-21 control information from a programmable logic control and reference information at inputs 12-16 from plant interlocks. This information passes via opto-isolators 40 and buffers 41 to the address bus of an EPROM so as to access information stored therein which normally mirrors the PLC information so as to control relays RL1-5 via drivers 45 to conform to the PLC instructions. The EPROM also contains reset and clock information for use by a counter 48 which allows different areas within the EPROM to be accessed. The reset information is also available to a parity check circuit 49 via oscillator 46 for dynamically testing the monitor for integrity of operation. Failure of the PLC or monitor components will cause access to shutdown addresses of the EPROM and operation of the appropriate relays including lockout relay RL6.

each stage of the burner sequence. If there is a discrepancy, appropriate action can be initiated.

If the high air purge is less than the minimum time then power will be taken off T1 before it can time out, so the check input will not go high. The check input can be used as a clocking condition, so that if incorrect timing results, the EPROM is accessed at the wrong location, and shutdown will result.

This is illustrated in Figure 17. Here, because the check input has not gone high, the EPROM will not be stepped on. This has therefore checked the length of the purge.

The next time that can be checked is the pilot ignition time to confirm it does not exceed 5 seconds. Figure 18 shows the effect of an extended pilot ignition time. The ignition is on at the same time as the check input which means the pilot ignition period has exceeded 5 seconds.

This address can be pre-programmed as disallowed in the EPROM, and can contain a shutdown instruction. If the pilot ignition period is less than 5 seconds then the address word would be allowed, as shown in Figure 16.

The Main ignition time can be checked on timer T3 as seen from Figure 16. This timer is energised when the main valve output is energised and will then time out after 5 seconds, by which time the pilot should have been extinguished. However, if the pilot stays on for longer than 5 seconds, then when timer T3 times out, the pilot output will still be energised. This is shown in Figure 19. This can be pre-programmed as a disallowed address and so contain a shutdown instruction.

This configuration has thus checked the purge time, pilot ignition time and the Main ignition time.

The timers can be configured by standard preset solid state timers. If any timer should fail then any error will be picked up by the check input of the EPROM address line and appropriate action instigated.

The EPROM used in the monitor system can be pre-programmed with data at its various locations using standard techniques or by the use of a short program.

Claims

1. A monitor system for monitoring a micro-processor based control device in safety critical situations, said system including :-
first input means for receiving control information from the microprocessor based control device;
second input means for receiving reference information also received by said control device;
means for determining whether the control information from said device corresponds to that expected in view of the reference information, and means for overriding the control information if any error in this control information is detected.

2. A system as claimed in claim, wherein the

determining means includes a memory for storing binary data accessible in dependence on information received from the first and second input means.

3. A system as claimed in claim 2, wherein the memory comprises a ROM for receiving information derived from the control device and said reference information so as to address locations therein.

4. A system as claimed in claim 2 or 3, wherein the memory is configured to contain information mirroring the control device information and to contain overriding information, the information mirroring the control device information being located at addresses accessible during normal operation of the control device and the overriding information being located at addresses accessible during an error phase of the control device.

5. A system as claimed in claim 4, including selector means, and wherein the memory has sufficient capacity to store additional sequencing information for receipt by the selector means to cause different memory areas to be made available to the control device information and reference information.

6. A system as claimed in claim 5, wherein the selector means includes a counter, and wherein feedback means are provided from the data bus of said memory to reset or increment the counter in dependence on preprogrammable instructions within selected memory storage locations.

7. A system as claimed in any of one of claims 2 to 6, wherein the first and second input means include opto-isolators for electrically isolating the inputs and including buffers for converting the inputs to a level suitable for the address bus of the memory.

8. A system as claimed in any one of claims 2 to 7, wherein the second input means are configured to receive thermostat, air status input and flame presence information from a burner device.

9. A system as claimed in any one of claims 2 to 8, wherein the first input means is configured to receive fan, ignition, pilot, main, and alarm information from the control device for burner control.

10. A system as claimed in any one of claims 1 to 9, including checking means provided to ensure the integrity of the monitor system is maintained.

11. A system as claimed in claim 10, wherein the checking means include a dynamically operable check circuit for continually checking system integrity.

12. A system as claimed in claim 11, including a controllable oscillator for dynamically exercising the parity of the check circuit and a lockout device for initiating operational lockout in the event of a detected failure.

13. A system as claimed in claim 12, wherein the oscillator is controlled by an output provided by the determining means.

14. A system as claimed in claim 12 or 13, including at least one relay and a relay operating circuit under the control of a signal derived from the oscillator to establish the integrity of the at least one relay.

5

15. A system as claimed in claim 14, wherein the at least one relay includes a bistable lockout relay having a first coil operable to a lockout condition on receipt of an error detection signal from the parity check circuit, said relay being resettable by means of a second coil.

10

16. A system as claimed in any preceding claim, including relay means operable in dependence on an output derived from the determining means to interrupt the passage of control information from the control device to a remote location.

15

17. A system as claimed in claim 16, wherein the relay means are operable to by-pass the monitor in the event of monitor failure.

20

18. A system as claimed in any preceding claim, including timer means operable to provide reference sequencing information for use by the determining means.

19. A monitor system for monitoring a micro-processor based control device substantially as described herein with reference to the accompanying drawings.
